# Remote debugging with IDA Pro. © DataRescue 2005

Since version 4.8, IDA Pro supports remote debugging of x86/AMD64 Windows PE applications and Linux ELF applications over TCP/IP networks. Remote debugging is the process of debugging code running on one networked computer from another networked computer:

- The computer running the IDA Pro interface will be called the "debugger client".
- The computer running the application to debug will be called the "debugger server".

Remote debugging will be particularly useful in the following cases:

- To debug virus/trojans/malwares : in this way, the debugger client will be as isolated as possible from the compromised computer.
- To debug applications encountering a problem on one computer which is not duplicated on other computers.
- To debug distributed applications.
- To always debug from your main workstation, so you won't have to duplicate IDA configuration, documentation and various debugging related resources everywhere.
- In the future, to debug applications on more operating systems and architectures.

This small tutorial will present how to setup and use remote debugging in practice.

# The remote IDA debugger server.

In order to allow the IDA client to communicate with the debugger server over the network, we must first start a small server which will handle all low-level execution and debugger operations. The IDA distribution ships with a Windows debugger server (the *win32\_remote.exe* file) and a Linux debugger server (the *linux\_server* file). With these, we can:

- Locally debug x86/AMD64 Windows applications and DLLs from the IDA Windows graphical and text versions.
- Remotely debug x86 Linux applications and shared libraries from the IDA Windows graphical and text versions.
- Locally debug x86 Linux applications and shared libraries from the IDA Linux text version.
- Remotely debug x86/AMD64 Windows applications and DLLs from the IDA Linux text version.

So let's first copy the small Windows debugger server file to our debugger server.

This server accepts various command line arguments:

```
C:\> win32_remote -?
IDA Windows32 remote debugger server. Version 1.0. Copyright Datarescue 2004
Error: usage: ida_remote [switches]
-p... port number
-P... password
-v verbose
```

Let's start it by specifying a password, to avoid unauthorized connections:

```
C:\>win32_remote -Pmypassword
IDA Windows32 remote debugger server. Version 1.0. Copyright Datarescue 2004
Listening to port #23946...
```

Note that the remote debugger server can only handle one debugger session at a time. If you need to debug several applications simultaneously on the same host, launch several servers on different network ports by using the -p switch.

### Setting up the debugger client.

First, we copy the executable we want to debug from the debugger server (Windows or Linux) to the debugger client (Windows or Linux). We can then load this file into IDA, as usual. To setup remote debugging, we select the '*Process options*...' menu item in the *Debugger* menu:

Debug application setup	×
Application C:\IDA\wingraph32.exe	•
Input file C:\IDA\wingraph32.exe	•
Directory C:\IDA\	•
Parameters	•
Hostname dbgserver.test.net  Port 23946 Password  mypassword	
O <u>K</u> Cancel Help	

Specify the *Application*, *Directory* and *Input file* paths. Note that these file paths should be valid on the remote debugger server. Also do not forget to enter the host name or IP address of the debugger server: remote debugging will only be enabled if these settings are specified ! Finally, we enter the password we chose for the remote IDA debugger server.

#### Starting remote debugging.

Both debugger server and debugger client are now ready to start a remote debugging session. In fact, you can now use all debugger related commands as you would with the local Windows PE debugger or local Linux debugger! For example, we can run the process until EIP reaches the application entry point, by jumping to this entry point then pressing the F4 key:

📑 ID	A View-EIP				Ge	eneral regi	sters	
	.text:00401634	hInst=	dword ptr 8	ась 📥	EAX	00400000	₩ wingraph32.exe:unk_40000	CF 0
	.text:00401634	lpszCmd	Line= dword ptr	r –	EBX	0013308B	4 debug021:unk_13308B	PF 1
	.text:00401634	nCmdSho	w= dword ptr	14h	ECX[	0012FFB0	➡ Stack[000001D8]:0012FFB0	AF 0
EIP 🔸	.text:00401634	push	ebp		EDX	784AF170	▶ ntdll.dll:784AF170	ZF 1
	.text:00401635	mov	ebp, esp		ESI	004CB034	Lata:off 4CB034	SF 0
	.text:00401637	add mov	esp, UFFFFFD eax, offset st	4n tru	EDI	00000000	L	TF 0
	.text:0040163F	push	ebx		EBP	0012FFB8	L Stack[000001D8]:0012FFB8	IF 1
	.text:00401640 .text:00401641	push push	esi edi		ESP	0012FF8C	➡ Stack[000001D8]:0012FF8C	DF
•	.text:00401642	call	<pre>@InitExceptB</pre>	B10	EIP	00401634	▶ WinMain	OF
	•			•	EFL	00000246		

If we now directly terminate the process (by pressing CTRL-F2) and look at *win32\_remote*'s output (on the debugger server), we indeed properly observe it accepted then closed our network connection:

```
C:\> win32_remote -Pmypassword
IDA Windows32 remote debugger server. Version 1.0. Copyright Datarescue 2004
Listening to port #23946...
Accepting incoming connection...
Closing incoming connection...
```

Another interesting possibility is to attach to an already running process on the remote computer. If you click on the '*Attach to process...*' command from the Debugger menu, IDA will display a listing of all remote running processes corresponding to the file in your disassembly database:

Choose process to attach to						
ID	Name					
16576	wingraph32.exe					
1						
OK	Cancel	Help	Search			
Line 1 of 1						

Double clicking on a process from the list will automatically suspend the process and attach to it, allowing you to debug it without starting it manually. This attach process works from Windows to Linux, from Windows to Windows, from Linux to Linux and from Linux to Windows.

# Detaching from the debugged process.

Finally, if the debugger server is running Windows XP, Windows Server 2003 or Linux, you can also detach from a process you were currently debugging, simply by using the '*Detach from process*' command in the *Debugger* menu:

PIDA - C:\wingraph32.exe - Running							
File Edit Jump Search View	Debugger Options Windows He						
Debugger: Library loaded Debugger: Library loaded Debugger: Library loaded	<ul> <li>General registers</li> <li>Segment registers</li> <li>FPU registers</li> <li>Threads list</li> <li>Modules list</li> </ul>						
AU: idle Down Disk: 28Gi	<ul> <li>Continue process Attach to process</li> <li>Process options</li> <li>Pause process</li> <li>Terminate process Ctrl+F2</li> <li>Detach from process</li> </ul>						

IDA supports debugging of DLLs on Windows and shared libraries on Linux. On Windows, please note that IDA can also attach to Windows services running either locally or remotely. In particular, the '*Detach from process*' command will be especially useful if you previously attached to a Windows service: it will allow you to stop the debugger without terminating a critical Windows service on the debugger server!
